Abstract:
Glycosyl hydrolases hydrolyze the glycosidic bond in carbohydrates or between a carbohydrate and a non-carbohydrate moiety. β-glucuronidase (GUS) is classified under two glycosyl hydrolase families (2 and 79) and the family-2 β-glucuronidase is reported in a wide range of organisms, but not in plants. The family-79 endo-β-glucuronidase (heparanase) is reported in microorganisms, vertebrates and plants. The E. coli family-2 β-glucuronidase (uidA) had been successfully devised as a reporter gene in plant transformation on the basis that plants do not have homologous GUS activity. On the contrary, histochemical staining with X-Gluc was reported in wild type (non-transgenic) plants. Data shows that, family-2 β-glucuronidase homologous sequence is not found in plants. Further, β-glucuronidases of family-2 and 79 lack appreciable sequence similarity. However, the catalytic site residues, glutamic acid and tyrosine of the family-2 β-glucuronidase are found to be conserved in family-79 β-glucuronidase of plants. This led to propose that the GUS staining reported in wild type plants is largely because of the broad substrate specificity of family-79 β-glucuronidase on X-Gluc and not due to the family-2 β-glucuronidase, as the latter has been found to be missing in plants.

Keywords: glycosyl hydrolase; β-glucuronidase; heparanase; endogenous GUS activity

Background:
Glycosyl hydrolases (GH) are a widespread group of enzymes hydrolyzing the glycosidic bond between two or more carbohydrates or between a carbohydrate and a non-carbohydrate moiety. GH was classified traditionally based on their substrate specificity. However, the classification based on substrate specificity was complicated by the fact that some enzymes hydrolyze more than one substrate. This resulted in reorganization of glycosyl hydrolases into families based on amino acid sequence similarities and intends to better reflect the structural features of these enzymes than their sole substrate specificity [1]. At present there are about 113 GH families that are available on the continuously updated Carbohydrate Active enZYmes (CAZy) web server [2]. β-glucuronidase (GUS) is a well characterized glycosyl hydrolase classified under two GH families, 2 and 79 respectively (CAZy). The enzyme catalyzes the hydrolysis of β-glucuronic acid residues from the non-reducing termini of glycosaminoglycans (GAGs). The reaction catalyzed by β-glucuronidase is, β-D-glucuronide + H₂O → D-glucuronate + alcohol.

The family-2 β-glucuronidase sequence was reported in a wide range of organisms, this include Homo sapiens, Rattus norvegicus, Drosophila melanogaster, Penicillium canescens and Escherichia coli. However, family-2 β-glucuronidase sequence has been so far not reported in plants. The family-79 β-glucuronidase had been characterized in Homo sapien and was known as heparanase, it is involved in the hydrolysis of heparan sulfate, a proteoglycan [3]. Apart from vertebrates, heparanase homologous sequence had been reported in a few microorganisms and in plants as well (Scutellaria baicalensis, Arabidopsis thaliana, Oryza sativa, Hordeum vulgare and Medicago truncatula). Referring to family-2 glucuronidase, the E. coil GUS encoded by (uidA) had been used for the development of a reporter gene system for plant transformation experiments [4]. Transgenic plants expressing E. coli GUS resulted in histochemical staining with the substrate 5-Bromo-4-chloro-3-indolyl-beta-D-glucuronide (X-Gluc) on GUS assay at the physiological pH (7.0). The enzyme GUS cleaved the β-glucuronic acid from the substrate X-Gluc and resulted in the development of a blue color of the transformed tissues. However, the untransformed/wild type plant remained unstained due to the absence of uidA activity. Jefferson and coworkers had also reported the absence of endogenous GUS activity in a broad spectrum of higher plants [5]. On the contrary, endogenous GUS activity evidenced by blue staining with X-Gluc had been reported in wild type (untransformed) plants particularly in immature tissues of a few species. The GUS activity was found to be present in male gametophyte of several solanaceous plants [6]. Similarly an extensive study of 52 seed-plants species showed that plants lack GUS activity in vegetative organs but has activity in reproductive tissues [7]. Alwen and coworkers reported endogenous GUS activity at pH 5.0 in a wide variety of plant species [8]. Further, the presence of endogenous GUS activity had been reported in...
vegetative and floral organs of *Arabidopsis thaliana* at pH 5.0 [9]. Above all, characterization of endogenous GUS activity in selected models such as *Arabidopsis thaliana*, *Oryza sativa*, *Zea mays* and *Nicotiana tabacum* clearly demonstrated the ubiquitous presence of GUS activity at an optimum pH of 4.0 [10]. In the light of reports on histochemical staining in wild type plants, the present study aim to resolve the basis for GUS staining in plants. We took to bioinformatics approach and analyzed the amino acid sequences of β-glucuronidases from family-2 and family-79. As an outcome of this study, we propose the absence of family-2 β-glucuronidase in plants and implicate family-79 β-glucuronidase (heparanase) for the alleged histochemical activity in wild type plants.

**Methodology:**
The GeneBank and GenPept databases of National Centre for Biotechnology Information (NCBI) and the Carbohydrate-Active enZymes server (CaZY) were accessed for this study [11]. Amino acid sequence of β-glucuronidase (family-2): *Homo sapiens* (NP_000172), *Escherichia coli* K12 (AAC74689), *Penicillium canescens* (AAV91787) and β-glucuronidase (family-79): *Homo sapiens* (AAD54516), *Scutellaria baicalensis* (BAA97804), *Arabidopsis thaliana* (BAB09947), *Oryza sativa* (BAD36026), *Hordeum vulgare* (CAD42650), *Medicago truncatula* (ABE93308) were downloaded from GenPept. Pairwise sequence alignment was done using align program with BLOSUM62 matrix [12]. The search for β-glucuronidase (family-2) homolog in plants was performed with PSI-BLAST and TBLASTN programs [13]. Multiple sequence alignment of the heparanase sequences was done using ClustalW [14]. The chemical structures of X-Gluc and Baicalein 7-O-β-D-glucuronide were retrieved from PubChem database [15].

**Figure 1:** A segment of the multiple sequence alignment of plant heparanase from *Oryza sativa*, *Medicago truncatula*, *Arabidopsis thaliana*, *Hordeum vulgare* and *Scutellaria baicalensis* is shown. The conserved catalytic site residues (glutamic acid and tyrosine) are shown in boxes.

**Figure 2:** Structure of (a) Baicalein 7-O-β-D-glucuronide and (b) X-Gluc showing the glucuronate moiety present in common (encircled).
Hypothesis

\[ \beta \text{-glucuronidase sequences belonging to family-2 and 79 reflected the existence of only a weak similarity/identity at the amino acid level. Pairwise alignment of human heparanase (family-79) and human } \beta \text{-glucuronidase (family-2) showed only 11.4% identity and 18.7% similarity. Similarly, human heparanase and } \text{E. coli } \beta \text{-glucuronidase (family-2) had only 11.7% identity and 22.0% similarity. In contrast, human and } \text{E. coli } \beta \text{-glucuronidase of family-2 shared significant level of identity (42.6%) and similarity (55.6%) despite their distance of separation in evolution. This impelled us to note that } \beta \text{-glucuronidase classified under the glycosyl hydrolase families (2 and 79) are two distinct categories of enzymes. Here we wish to discuss the role of } \text{E. coli family-2 } \beta \text{-glucuronidase } (uiddA) \text{ as a reporter gene in plant transformation experiments [5]. The alleged absence of homologous GUS activity in plants formed the basis for successfully devising one such system. In fact, til date there have been no reports on gene sequence cloned/annotated to encode for family-2 } \beta \text{-glucuronidase in plants. However, to belie this, there are a few reports on GUS activity in wild type plants, as revealed by histochemical staining with X-Gluc [6, 7, 8, 9, 10]. To resolve the basis for GUS staining, we searched the GenBank for plausible nucleotide sequences that are homologous to the members of family-2 } \beta \text{-glucuronidase in plants. PSI-BLAST which helps to find distantly related members was carried out with family-2 } \beta \text{-glucuronidase from } \text{E. coli, Penicillium, Homo sapiens and other organisms as query, but the search failed to detect corresponding homolog in plants. Subsequently, a translated BLAST (TBLASTN) search was done against the whole genome sequences of } \text{Arabidopsis thaliana} \text{ and } \text{Oryza sativa} \text{ using the same query sequences. However, the search failed to detect homologous sequence in plants. This hinted that, catalytic site of glucuronidase has been so conserved in } \text{Arabidopsis thaliana} \text{ and } X \text{-Gluc, it is evident that ‘} \beta \text{-glucuronate’ is the only common moiety found in the above two structures (Figure 2). Heparanase, may therefore bind either with } \text{Baicalein 7-O-} \beta \text{-D-glucuronide or X-Gluc via the glucuronate moiety and result into hydrolysis of the glycosidic bond. The above hypothesis further qualifies from the fact that glycosyl hydrolases in general were known to possess broader substrate specificity [1].}

Conclusion:

The gene encoding for family-2 } \beta \text{-glucuronidase has been so far not reported in plants. However, it was known to be present in different groups of organism such as archaeabacteria, eubacteria, fungi, invertebrates and vertebrates. Our search to find family-2 } \beta \text{-glucuronidase homologous sequence in plants turned out to be unsuccessful, suggesting that family-2 GUS could be missing in plants. Further, analyses of family-2 and family-79 } \beta \text{-glucuronidases provided a sequence based functional insight on the origin of histochemical staining in wild type plants. The proposed broad substrate action of family-79 } \beta \text{-glucuronidase on X-Gluc explains the basis for GUS staining reported in wild type plants at low pH. However, the absence of histochemical staining at physiological pH is on expected lines, as plant heparanase was known to have acidic pH for its optimal activity. On the other hand, family-2 } \beta \text{-glucuronidase works only at pH 7.0 and transgenic plants overexpressing GUS contributes for the histochemical activity, the absence of GUS staining in wild type plants at the physiological pH confirms that family-2 } \beta \text{-glucuronidase is missing in plants.}
